

Event-driven Architecture

Event-driven Architecture is a programming paradigm where the flow of execution is determined by events (signals, messages, I/O readiness) rather than sequential execution.

The program sits iddle until something happens, then responds to that specific event.

Event Loop

The Event Loop is the core of Event-driven Architecture.

It's an infinite loop that:

- Waits for events (using poll/select/epoll)
- Dispatches events to appropriate handlers
- Returns to waiting
